# Device troubleshooting guide

## Slow device checklist

This fictional Northstar IT manual is demonstration data, not real device-management advice for an employer.

For a slow device, save your work, close unused applications, and restart the device. Check that at least 20 GB of disk space is available.

Use the approved system update tool to check pending updates. Do not remove security software to improve performance.

If the problem continues, submit an IT ticket containing the device ID, affected applications, and the approximate start time.

## Wi-Fi connection checklist

Confirm that airplane mode is off and Wi-Fi is enabled. Select the approved network and reconnect once.

If other devices can connect but your managed device cannot, restart your device and contact IT support if the issue continues.

If several employees lose access at the same time, report the affected location so IT can check for a wider network incident.

Do not share network passwords in support tickets.
